# Elgamal CryptoSystem

Murat Kantarcioglu

# Cryptosystems Based on DL

---

- DL is the underlying one-way function for
  - Diffie-Hellman key exchange
  - DSA (Digital signature algorithm)
  - ElGamal encryption/digital signature algorithm
  - Elliptic curve cryptosystems
- DL is defined over finite groups

# Discrete Logarithm Problem

---

- Let  $p$  be a prime and  $\alpha$  and  $\beta$  be nonzero integers in  $Z_p$  and suppose

$$\beta \equiv \alpha^x \pmod{p}.$$

- The problem of finding  $x$  is called the discrete logarithm problem.
- We can denote it as

$$x = \log_{\alpha} \beta$$

– Often,  $\alpha$  is a primitive root mod  $p$

- Reminder:  $Z_p$  is a field  $\{0, 1, \dots, p-1\}$
- Addendum:  $Z_p^*$  is a cyclic finite group  $\{1, \dots, p-1\}$

# Example: Discrete Log

- Example:
  - Let  $p = 11$ ,  $\alpha = 2$ , and  $\beta = 9$ .
  - By exhaustive search,

<b>x</b>	0	1	2	3	4	5	<b>6</b>	7	8	9	10
$\alpha^x$	1	2	4	8	5	10	<b>9</b>	7	3	6	1

- $\log_2 9 = 6$ .
- $\beta \equiv \alpha^x \pmod{p}$ .

# Computing Discrete Log

---

- When  $p$  is small, it is easy to compute discrete logarithms by exhaustive search.
- However, it is a hard problem to solve for primes  $p$  with more than 200 digit.
- One-way function.
  - It is easy to compute modular exponentiation
  - But, it is hard to compute the inverse operation of the modular exponentiation, i.e. discrete log.

# The ElGamal PKC

- Based on the difficulty of discrete logarithm, was invented by Tahir ElGamal in 1985.
- Alice wants to send a message  $m$  to Bob.
- Bob chooses a large prime  $p$  and a primitive root  $\alpha$ .
  - Assume  $m$  is an integer  $0 < m < p$ .
- Bob also picks a secret integer  $a$  and computes
  - $\beta \equiv \alpha^a \pmod{p}$ .
- $(p, \alpha, \beta)$  is Bob's public key.
- $(a)$  is his private key

# The ElGamal PKC: Protocol

---

Alice

Bob

Chooses a secret integer  $k$

Computes  $r \equiv \alpha^k \pmod{p}$

Computes  $t \equiv \beta^k \cdot m \pmod{p}$

Sends  $(r, t)$  to Bob.

Computes  $t \cdot r^{-a} \equiv m \pmod{p}$

This works since

$$t \cdot r^{-a} \equiv \beta^k \cdot m \cdot (\alpha^k)^{-a} \equiv (\alpha^a)^k \cdot m \cdot (\alpha^k)^{-a} \equiv m \pmod{p}$$

# Analysis of ElGamal PKC

---

- $a$  must be kept secret.
- $k$  is a random integer,
  - $\beta^k$  is also a random nonzero integer mod  $p$ .
  - Therefore,  $t \equiv \beta^k \cdot m \pmod{p}$  is the message  $m$  multiplied by a random integer.
  - $t$  is also a random integer
- Knowing  $r$  does not help either.
- If Eve knows  $k$ ,
  - she can calculate  $t \cdot \beta^{-k} \equiv m \pmod{p}$ .
  - $k$  must be secret

# Analysis of ElGamal PKC

---

- A different random  $k$  must be used for each message  $m$ .
  - Assume Alice uses the same  $k$  for two different messages  $m_1$  and  $m_2$ ,
  - the corresponding ciphertexts are  $(r, t_1)$  and  $(r, t_2)$ .
  - If Eve finds out the plaintext  $m_1$ , she can also determine  $m_2$  as follows
  - $t_1/m_1 \equiv \beta^k \equiv t_2/m_2 \pmod{p} \Rightarrow m_2 \equiv (t_2 m_1)/t_1$

# Semantic Security (IND-CPA for Public Key Encryption)

- The IND-CPA game

Challenger

Adversary

picks a random key pair  $(K, K^{-1})$ , and picks random  $b \in \{0, 1\}$

Attacker wins game if  $b=b'$

# Semantic Security of ElGamal

---

- Note that the generic ElGamal encryption scheme is **not semantically secure**.
- We can infer whether a ciphertext is **quadratic residue or not**.
- We can use the above fact to come up with two message where one of them is a quadratic residue and the other one is a quadratic non-residue so that attacker has **high advantage in distinguishing encryptions**.
- The above attack **does not work** if  $\beta$ , every plaintext is quadratic residue and  $p=2q+1$  where  $q$  is prime.
  - It can be shown that this version is **semantically secure** if DL is infeasible.

# CDH and DDH

- **Computational Diffie-Hellman (CDH)**
  - Given a multiplicative group  $(G, *)$ , an element  $\alpha \in G$  having order  $q$ , given  $\alpha^x$  and  $\alpha^y$ , find  $\alpha^{xy}$
- **Decision Diffie-Hellman (DDH)**
  - Given a multiplicative group  $(G, *)$ , an element  $\alpha \in G$  having order  $q$ , given  $\alpha^x$ ,  $\alpha^y$ , and  $\alpha^z$ , determine if  $\alpha^{xy} \equiv \alpha^z$
- Discrete Log is at least as hard as CDH, which at least as hard as DDH.

# CDH and ElGamal

- *Prove that any algorithm that solves CDH can be used to decrypt ElGamal ciphertexts*

- Proof Sketch: “ $\Rightarrow$ ” Assume that algorithm OracleCDH solves CDH and let  $(r, t)$  be an ElGamal encryption and let public key  $(p, \alpha, \beta)$  and  $r = \alpha^k \pmod p$

$\gamma = \text{OracleCDH}(\alpha, \beta, r)$  and

$m = t \gamma^{-1}$  then  $m$  is the decryption of  $(r, t)$

# DDH $\Rightarrow$ ElGamal

- Given DDH oracle, find two messages whose ElGamal encryptions can be distinguished
- For any two  $m_0, m_1$ : ( $\beta = \alpha^a$ )
  - $E(m_0) = \alpha^{k_1}, m_0 \beta^{k_1}$ ,  $E(m_1) = \alpha^{k_2}, m_1 \beta^{k_2}$
  - Suppose receive ciphertext  $(r, t)$
  - Feed  $\langle r, \beta \alpha^b, (t r^b)/m_0 \rangle$
  - when  $(r, t)$  is  $E(m_0)$ , this is  $\langle \alpha^{k_1}, \alpha^{a+b}, (m_0 \alpha^{k_1 a} \alpha^{k_1 b})/m_0 \rangle$   
 $= \langle \alpha^{k_1}, \alpha^{a+b}, \alpha^{k_1(a+b)} \rangle$ 
    - when  $(r, t)$  is  $E(m_1)$ , this is  $\langle \alpha^{k_2}, \alpha^{a+b}, (\alpha^{k_2(a+b)} m_1)/m_0 \rangle$
  - if the DDH oracle say yes, we say 0, otherwise we say 1
